

User behavior pattern:

Repeatedly submit instructions with **similar content** and **vague expressions** to the AI image generation model, asking it to make **multiple modifications** to a specific detail of the same image.

75% of Chinese users make more than 3 adjustments!

How to make users aware of the problem?

1. **AI detects the pattern**

   Detection Logic:
   Repeated revision prompt words
   Vague vocabulary (such as "a little", "some")

2. **Visualize the Power**

Power → Heat production → vaporization of liquid → fog density

Virtual icons: The mist effect displayed on the phone interface is better when there is more of it, and the denser the mist, the better.

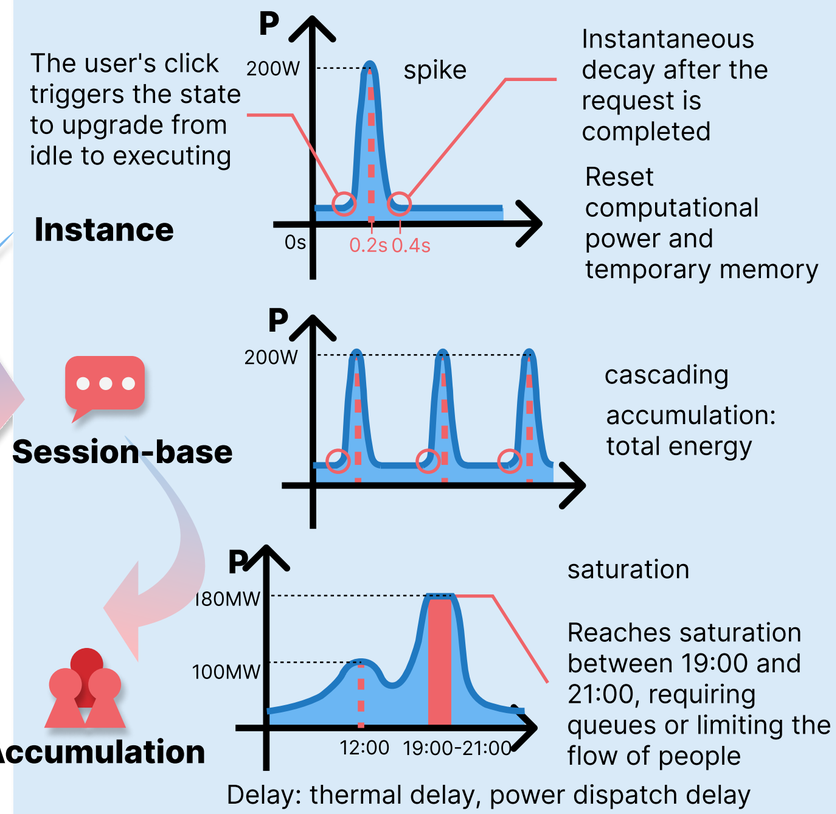
Physical device: Concentration of mist in a transparent box

Why Convenience?

VS Express the needs in one conversation → Replacing the language labor of clarifying instructions → **Repeated ★ Iterative**

VS PS: Using Photoshop → Replacing the manual labor of image editing → **Convenience-driven**

How is the energy consumption of such iterative AI usage behavior accumulated at both individual and system levels?



Why is such a huge energy consumption invisible to users?

Prioritize user experience, separate the interface from the underlying infrastructure, adopt commercial strategies ...
